9. Concluding Remarks

Introduction

The existence of long-living or even stable two barion systems(called as dibarion in this presentation) was and is one of the serious problems in particle physics overworld. In JINR this problem was being discussed by many theoreticians(D.Blokhintsev,A.Baldin,A.Efremov and many others) and was central for some experimentators (B.Shahbazian,

Yu.Troyan,...).Many physicists think that such states do not exist and in their argumentation they say that if they were existed the cross sections of NN - > NN interactions would show some irregularites(or peaks) at some energies.

In a figure below(produced by PDG group) we show the cross section of pn interaction as a function of the energy. The region between two vertical lines in this picture corresponds to two-nucleon interaction below pion production.

You may see that there are at least two rooms where the situation is unclear and should be carefully investigated.

Similar problems were discussed in the presentation of B.Kostenko to this conference.

In the current work we are trying to answer the question: Is the resolution of SPD detector enough for the search of dibarions?

Introduction, Conditions of the study

So we are talking about X systems ,produced in the reactions d + d - > d + X with consequent decay X - > p + n,with mass $MX = M_d + E_{exc}$ and $E_{exc} < m_{\pi^0}$ mass. Conditions of the study equivalent to the experiment Baldin et al.,Communication of the JINR, Dubna 1979,1-12397

- Momenum is 2.6GeV/c,equivalent to 8.9 on fixed target
- Transferred momentum of unbroken deuteron $t = -0.5(GeV/c)^2$
- *E_{exc}* is taken as a fractons of π⁰ mass equal to 1/4,1/2,3/4(or masses 1.90935,1.9421,1.97685 in GeV)
- All the collisions are taking place in central point of detector(coordinates x = y = z = 0),deuteron and proton tracks and primary vertex are reconstructed and dibarion has zero decay width.

Introduction, Results of Baldin experiment

What is Resolution?

Under the resolution we understand the width of the distribution(or a signal) of mass estimates of X. In electronics the width of any signal is characterized by so called FWHM(Full Width at Half Maximum) and if the signal is pure Gaussian, sigma of this Gauss is $1.18 \cdot \sigma = 1/2FWHM$. So we may specify the resolution as a σ of the Gaussian function approximating peak region of MX distribution.

Peak region here is selected by eye and the quality of such a selection can be seen below in a number of figures.

On the other hand we may use standard deviations(RMS). So we cite the resolution in both ways though we consider citing by σ 's preferable

Gauss with mean = 0 and σ :

$$\exp(-0.5(x/\sigma)^2) = 1 \ at = 0$$

 $\exp(-0.5(x/\sigma)^2) = 1/2 \ at = \approx \pm 1.18\sigma_{\text{constraint}} = 2000$

Modification of SpdRoot software

SpdRoot is currently the main package for events simulation and reconstruction for the SPD project. It is based on FairSoft / FairRoot package. The transport of the particles through the material and magnetic field of the SPD setup was supplied by Geant4. Track fitting was performed using the GenFit toolkit . Two modifications were performed : in a track fitting and in Tof processing.

Track Fitting

Earlier, Fit parameters were being obtained in first hit of the track. For the events when primary vertex was found its coordinates were added as additional hit to track hits and track was refitted to get Parameters at the vertex.

Tof modifications

The aim of this is to get length and time of flight of each particle from primary vertex to its hitting point in Tof detector.

Processing and fitting Event samples

After reconstruction of event, we have the following observables

- 1. Three momenta of deuteron and proton
- 2. Length and time of flight for deuteron and proton

Certainly the estimation should be done according to Maximum Likelihood Method and Total Likelihood Function is the production of 3 Likelihood functions

$$L_{tot} = L_{(Tofd - Tofp)} \cdot L_{\vec{p_d}} \cdot L_{\vec{p_p}}$$
(1)

Here $L_{(Tofd-Tofp)}$ is Likelihood function for the difference of Tof's for deuteron and proton and we should say few words about it. If we measured the time of event origin then for Tof of deuteron we would have the following expression :

$$Tof_d = (t_d^s - I_d / v_d) \tag{2}$$

Here t_d^s - simulated tof of deuteron, I_d , v_d - simulated flight length and velocity of deuteron, directly depending on the module of deuteron momentum. We can say the same words about

$$Tof_p = (t_p^s - l_p/v_p)$$

. Tof system of Spd is measuring the times of deuteron and proton hits, otherwise we have the difference $Tof_d - Tof_p$ and can use it at the parameters estimation. Let us denote this difference as Tof_{dif}^m . We may write for $L_{(Tofd-Tofp)}$ the following:

$$L_{(Tofd-Tofp)} \approx \exp\left(-1/2 \cdot \left(\left((Tof_d - Tof_p) - Tof_{dif}^m\right)/\sigma_{dif}\right)^2\right)$$
(3)

here $\sigma_{dif} = \sqrt{2} \cdot \sigma_{tof}$, where σ_{tof} is the error of tof measurement equal to 60ps.

Processing and fitting Event samples, continued, 1

 $L_{\vec{p_d}}$ and $L_{\vec{p_p}}$ are due to the measurements from Vertrex and Straw Detectors (Let us call them as Track Detectors - TD). So for $L_{\vec{p_d}}$ we have

$$L_{\vec{p_d}} \approx \exp\left(-1/2 \cdot \left(\vec{p_d^t} - \vec{p_d^m}\right) \cdot Cov_d^{-1} \cdot \left(\vec{p_d^t} - \vec{p_d^m}\right)^T\right) \qquad (4)$$

 p_d^{t} is three momentum of deuteron (parameters to be found) and $p_d^{\vec{m}}$ is its estimate found during track reconstruction. The latter and Cov_d^{-1} are found by GenFit2 code during track reconstruction. Analogously for proton

$$L_{\vec{p_p}} \approx \exp\left(-1/2 \cdot \left(\vec{p_p^t} - \vec{p_p^m}\right) \cdot Cov_p^{-1} \cdot \left(\vec{p_p^t} - \vec{p_p^m}\right)^T\right)$$
(5)

 $\vec{p_p^t}, \vec{p_p^m}, \textit{Cov}_p^{-1}$ have the same meaning explained above but for proton

Processing and fitting Event samples, continued, 2

As was said above the estimates of parameters should be found by maximizing the function of (1) or equivalently by minimizing the function (6)

$$\chi^{2} = (((Tof_{d} - Tof_{p}) - Tof_{dif}^{m}) / \sigma_{dif})^{2} + (\vec{p_{d}^{t}} - \vec{p_{d}^{m}}) Cov_{d}^{-1} (\vec{p_{d}^{t}} - \vec{p_{d}^{m}})^{T} + (\vec{p_{p}^{t}} - \vec{p_{p}^{m}}) \cdot Cov_{p}^{-1} \cdot (\vec{p_{p}^{t}} - \vec{p_{p}^{m}})^{T}$$
(6)

But there is one more thing which should be taken into account,namely: in addition to 2 charged particles(deuteron and proton) there is undetected neutron in a final state. It means that missing mass of the reaction should be equal to neutron mass. In other words we can do constraint fitting(see below) to find best estimates of deuteron and proton momenta.

So, number of observables is 7, number of parameters(Three Momenta of deuteron and proton to be found, otherwise $\vec{p_d^t}$ and $\vec{p_p^t}$) is 6 Fitting was done by Fumili code(S.N. Sokolov, I.N. Silin,Preprint JINR D-810,Dubna). Originally it was written in FORTRAN and rewritten later in C.

There are three methods of constrained minimization(To be short methods are named more or less arbitrarily):

- 1. Lagrange's multiplier method
- 2. Minimization with Heavy Term
- 3. Minimization with the change of parameter increments

Lagrange's multiplier method(J.P. Berge,F.T. Solmitz,H.D. Taft,Rev. Sci. Instr. 32(1961)538) is the first one where constraint fitting in the particle physics was proposed. It is named after Lagrange who proposed the method for finding the extreme of the functions of many variables with the constraints.

Second method was proposed by V.I.Moroz(V.I. Moroz, JINR, P-1958,1965), when bubble chambers were one of the main instruments in particle physics and it is related with the use of Fumili proposed earlier.

Finally third method was proposed(Nucl. Instr. and Meth. **A345**(1994)346) in 1994.

In the current work 2-nd method was used due to its quick realization!

Methods for the Dibarion Mass estimations - 3 Options

Using TD we can measure 3-momentum of deuteron - $\vec{p_d}$, or its 4-vector P_d^4 . On the other hand we know mass of the reaction(mass of two colliding deuterons), let denote its 4-vector as M_R^4 . Then we may try to see dibarions just by calculating missing mass:

$$M_X = (M_R^4 - P_d^4).M()$$
(7)

If the resolution of TD were sufficiently high(below we show it as the result of the simulation), we would see some peaks in missing mass distribution. We did it in our analysis and let us call it as an Option 1.

On the other hand Spd is measuring also P_p^4 and the difference $Tof_d - Tof_p$. If in addition to the information about the deuteron and proton from TD system we add $Tof_d - Tof_p$ we can try to find the other estimates of deuteron and proton momenta(by the minimization of function (6)) and then analyze missing mass distribution, calculating it by the same formula 7. Let us call it as an Option 2. Finally,we know that except of registered deuteron and proton there is unregistered neutron.

Then during minimization we should require the fulfilment of the following equation 8:

$$M_n^2 = (M_R^4 - P_d^4 - P_p^4).M2()$$
(8)

or should do so called constraint fit, in other words we should find momenta of deuteron and proton by minimizing function (6) with addition of the constraint in the form of missing mass equation 8. Here M_n^2 is square of neutron mass. We call it as an **Option 3**.

Resolution for $E_{exc} = m_{\pi^0}/4$ in different Options

The resolution of MX in a different Options

In three figures before we show histograms, demonstrating the distributions of MX obtained in different Options. Three distributions are shown in each picture. As you can see each distribution has a peak and near it we may select some region, where the distribution is practically Gaussian. By solid line we show the fit of such a regions by Gaus. Regions were selected by eye. Then we can do the comparison of the widths by its σ 's. On the other hand there are standard deviations(RMS), which also may characterize the widths of distributions. If we compare the results in Option2 and Option 3, we may say that for these three MX

- ▶ in terms of σ 's the width of MX distribution in the Option 3 in $\approx 75 - 100$ times less(or better) than in Option 2
- ▶ in terms of RMS the width of MX distribution in the Option 3 in $\approx 17 30$ times less than in Option 2

The resolution of MX in a different Options, continued 1

Fit in so called Option2 is a fit,taking into account all the information about event, but without constraint,fit in Option3 - the same but with addition of the constraint. In a table 1 we show the results of fitting in all the Options and RMS of distributions(in parentheses near fit results). Remember that the regions for a fitting are selected by eye!

$M_d - MX$	Option1(RMS)	Option2(RMS)	Option3(RMS)
-0.0338	$-0.05874 \pm 0.2181(0.2913)$	$-0.0545 \pm 0.2117(0.2874)$	$-0.0339 \pm 0.0020(0.0083)$
-0.0675	$-0.0929 \pm 0.2213(0.2911)$	-0.0753 ± 0.2043(0.2794)	$-0.0676 \pm 0.0027(0.0126)$
-0.1013	$-0.1097 \pm 0.2070(0.2845)$	$-0.1092 \pm 0.1986(0.2677)$	$-0.1014 \pm 0.0024(0.0151)$

Table: The results of fitting $(M_d - MX)$ in all the Options in the form mean $\pm \sigma$ for all MX's. RMS is shown in parenthesis . Everything in GeV

Concluding Remarks

- ► The resolution of Spd detector in the search of dibarions at the process d + d - > d + X, $M_d < MX < M_d + m_{\pi^0}$ under simplified assumptions looks very optimistic, the resolution is $\approx 2 - 3MeV$ in the dibarion mass. Such amazing resolution is achieved by the using kinematical fitting technique, giving improvement $\approx 75 - 100$ times in terms of σ 's compared with the estimation parameters without this technique.
- It deserves the starting of the planning real experiment with the attempt to answer many questions, some of them below
- At which Collider Momentum to do such a study?
- Which kinematical region(in a final state) is more promising for the search ?
- How to identify(select) the reaction d + d > d + p + n?
- And ...,et cetera
